Project Title	Restaurant Recommendation system
Maximum Marks	10 Marks

Model Optimization and Tuning Phase

The Model Optimization and Tuning Phase involves improving our machine learning recommendation model to get the best performance. This includes adjusting the model's parameters, experimenting with different algorithms, and selecting the most suitable model based on evaluation metrics such as accuracy, precision, recall, and RMSE (Root Mean Squared Error).

Our restaurant recommendation system was designed to suggest similar restaurants based on location, user ratings, cuisines, and cost using collaborative filtering and content-based filtering techniques.

Model Tuned Hyperparameters	
Model 1: Content-Based Filtering - Similarity Metric: Cosine similarity was used as the primary metric to compute similarity between restaurants based on features licuisines, rating, and cost. - Top N Recommendations: The number of top similar restaurants returned was tested with values like 5, 10, and 15.	ke

Hyperparameter Tuning Documentation (8 Marks):

```
dif recommend(name, cosine similarities - cosine similarities):
                                                     recommend_restaurant - []
                                                     idx - indices indices - name [ index[0]
                                                     score series - pd Series(cosine similarities[idx]) sort values(ascending-Pales)
                                                     top30_indexes = lint/score_series.iloc(0.31].index()
                                                      recommend_restaurant.append(list(df_percent.index)(each))
                                                     off new - pd.DataFrancecolumns-[commes], 'Mean Rating', 'conf])
                                                      df new - df new appendipd. DataFrame(df percent[] critinies (Mean Barting, Voirt | [[df percent index -- each] sample()))
                                                     # Deep the same ranged restorment, and sort only the top 10 by the highest rating df_new = df_new.deep_daphicates|subset=[comings, Mean Rating, cost], keep=False) df_new = df_new.sert_values(by=Mean Rating, ascending=False),head(10)
                                                     print(TOP - RESTAURANTS LIKE - WITH SIMILAR RIVIEWS : (or(len(df new)), name))
                                                     df new index - df new index str lower()
  Model 2:
                                        Algorithm: SVD (Singular Value Decomposition) from the Surprise
                                                                                    library.
Collaborativ
                                     Learning Rate: Tuned values such as 0.005, 0.01, and 0.02 were tested.
                         - Regularization: Parameters such as 0.02, 0.05 were tried to avoid overfitting.
   Filtering
                                                Number of Epochs: Adjusted between 20 and 100 epochs.
                                                     from surprise import SVD, Dataset, Reader
                                                     from surprise.model_selection import cross_validate
                                                     reader - Reader(rating_scale=(1, 5))
                                                    data = Dataset.load_from_df(df[['user_id', 'restaurant_name', 'rating']], reader)
                                                     svd = SVD()
                                                    cross validate(svd, data, measures=['RMSE', 'MAE'], cv=5, verbose=Trne)
```

Final Model Selection Justification(2Marks):

Final Model	Reasoning
Model 1: Content- Based Filtering	Selected due to its simplicity and good performance without requiring detailed user history. It gave interpretable and relevant results using restaurant features like cuisines, ratings, and cost.
